

## ABSTRACT

In an information display device, in which display media (particles or liquid powders) are sealed between opposed substrates, at least one substrate being transparent, and, in which the display media (particles or liquid powders), to which an electrostatic field is applied, are made to move so as to display information such as an image, spacers are arranged on a surface of at least one substrate in a sealing agent arranging portion, which seals a space between at least one flexible substrate and the other substrate by a sealing agent. Hereby, providing the information display device, in which an adequate gap endurable to a high-voltage application can be ensured, and a breakage of an information display panel can be suitably prevented.
